ABSTRACT
Targeted advertising is meant to improve the efficiency of matching advertisers to their customers. However, targeted advertising can also be abused by malicious advertisers to efficiently reach people susceptible to false stories, stoke grievances, and incite social conflict. Since targeted ads are not seen by non-targeted and non-vulnerable people, malicious ads are likely to go unreported and their effects undetected. This work examines a specific case of malicious advertising, exploring the extent to which political ads from the Russian Intelligence Research Agency (IRA) run prior to 2016 U.S. elections exploited Facebook’s targeted advertising infrastructure to efficiently target ads on divisive or polarizing topics (e.g., immigration, race-based policing) at vulnerable sub-populations. In particular, we do the following: (a) We conduct U.S. census-representative surveys to characterize how users with different political ideologies report, approve, and perceive truth in the content of the IRA ads. Our surveys show that many ads are “divisive”; they elicit very different reactions from people belonging to different socially salient groups. (b) We characterize how these divisive ads are targeted to sub-populations that feel particularly aggrieved by the status quo. Our findings support existing calls for greater transparency of content and targeting of political ads. (c) We particularly focus on how the Facebook ad API facilitates such targeting. We show how the enormous amount of personal data Facebook aggregates about users and makes available to advertisers enables such malicious targeting.

KEYWORDS
advertisements, targeting, social divisiveness, news media, social media, perception bias

1 INTRODUCTION
Online targeted advertising refers to the ability of an advertiser to select audience for their ads. Such advertising constitutes the primary source of revenue for many online sites including most social media sites such as Facebook, Twitter, YouTube, and Pinterest. Consequently, these sites accumulate detailed demographic, behavioral and interest profiles of their users enabling advertisers to “micro-target”, i.e., choose small (tens or hundreds to thousands) of users with very specific attributes like people living in a zipcode that read NewYorkTimes or Breitbart. Beyond raising numerous privacy concerns [13, 19], targeted ad platforms have come under scrutiny for enabling discriminatory advertising, where ads announcing housing or job opportunities are targeted to exclude people belonging to certain races or gender [1, 5, 7, 18].

In this paper, we analyze the potential for a new form of abuse on targeted ad platforms namely, socially divisive advertising, where malicious advertisers incite social conflict by publishing ads on divisive societal issues of the day (e.g., immigration and racial bias in policing in the lead up to 2016 US presidential elections). Specifically, we focus on how ad targeting on social media sites such as Facebook can be leveraged to selectively target groups on different sides of a divisive issue with (potentially false) messages that are deliberately crafted to stoke their grievances and thereby, worsen social discord. We also investigate whether targeted ad platforms allow such malicious campaigns to be carried out in stealth, by excluding people who are likely to report (i.e., alert site administrators or media watchdog groups about) such ads.

Our study is based on an in-depth analysis of a publicly released dataset of Facebook ads run by a Russian agency called Internet Research Agency (IRA) before and during the American Election on the year of 20161 2. Our analysis is centered around three high-level research questions:

RQ 1: How divisive is the content of the IRA ads? We quantify the divisiveness of an ad by analyzing the differences in reactions of people with different ideological persuasions to the ad. Specifically, using US census-representative surveys, we look at how conservative- and liberal-minded people differ in (a) how likely they are to report the ad, (b) how strongly they approve or disapprove the ad’s content, and (c) how they perceive truth (or falsehood) in ad’s claims. Our analysis shows that IRA ads elicit starkly different

1https://www.wsj.com/articles/you-cant-buy-the-presidency-for-100-000-1508104629

* These authors contributed equally to this work.
RQ 2: How effectively done was the targeting of the socially divisive ads? We find that the “Click Through Rate” (CTR), a traditional measure of effectiveness of targeting, of the IRA ads are an order of magnitude (10 times) higher than that of typical Facebook ads. The high CTR suggests that the ads have been targeted very efficiently. A deeper analysis of the demographic biases in the targeted audience reveals that the ads have been targeted at people who are more likely to approve the content and perceive fewer false claims, and are less likely to report.

RQ 3: What features of Facebook’s ad API were leveraged in targeting the ads? We also analyze the construction or specification of “targeting formulae” for the ads, i.e., the combination of Facebook user attributes that are used when selecting the audience for the ads. We find wide-spread use of interest attributes such as “Black Consciousness movement” and “Chicano movement” that are mostly shared by people from specific demographic groups such as African-Americans and Mexican-Americans. We show how Facebook ad API’s suggestion feature may be exploited by the advertisers to find interest attributes that correlate very strongly to specific social demographic groups.

1.1 Related Work
Prior studies have highlighted several forms of abuses of targeted advertising in Facebook, for inappropriately exposing users private information to advertisers [19] and for allowing discriminatory advertising (e.g., to exclude users belonging to a certain race or gender from receiving their ads) [18]. Differently, our effort highlights a new and different form of potential abuse of these platforms, that is the use of targeted advertising to create social discord.

Additional efforts have focused on understanding filter bubbles, echo chambers, and polarization in social media as an emergent phenomenon [4, 6, 8, 10, 11, 15]. We provide a complementary perspective about the topic by examining how echo chambers and polarization can be engineered on social media through targeted advertising. More closely related to our work, Kim et al. gathered Facebook ads from individuals and analyzed who are behind divisive ad campaigns, reporting suspicious foreign entities [12] Differently, we focus on the understanding the disruptive ability of microtargeting for providing divisive political ad campaigns.

Finally, our effort is complementary to prior work that attempts to understand the abuse of social media by misinformation campaigns, especially along political elections [14, 20]. Our work provides a better comprehension about a key dissemination mechanism of fake news stories, highlighting how advertising platforms allow injection of misinformation in social systems and choose vulnerable people as the target.

2 RUSSIA-LINKED FACEBOOK ADS DATASET
On May 10th, 2018 the Democrats Permanent Select Committee on Intelligence released a dataset containing 3,517 Facebook advertisements from 2015, 2016, and 2017 that are linked to a Russian propaganda group: Internet Research Agency (IRA).

Each ad is composed of an image and text, both of which were shown to Facebook users. Additionally, each ad contains a landing page, which is a link to the host of the ad, as well as an ad ID; an ad targeting formula, which is a combination of demographic, behavioral and user interest aspects used to target the Facebook users; the cost for running the ad in Russia Rubles; the number of impressions, which is the number of users who spent some time observing the ad, the number of clicks received by the ad; and, finally, the ad creation and end dates. This section provides an overview of these ads.

2.1 Time Distribution
The ads in the dataset were run between June 2015 and August 2017. From the 3,517 advertisements, we found that 617 (17.5%) were created in 2015, 1,867 (53.1%) in 2016, and 1,033 (29.4%) in 2017. Figure 1 shows the distribution of these ads over time in terms of number of ads created per month, cost to run the ads, and impressions and clicks received. Note that the y-axis is in log scale. We observed that the number of impressions, and clicks, increases almost an order of magnitude around the election period (shaded region). There is also another peak in February, just after the newly elected U.S. President Donald Trump assumed office.

2.2 Landing Pages
We first explore the ad landing pages: the urls to which users who clicked on the ads were redirected. There are 462 unique landing pages corresponding to all the ads. Figure 2 shows the top 10 landing pages per number of ads posted. The most popular landing page (fb.com//Black-Matters-1579673598947501/) posted 259 advertisements. Interestingly, one of the top landing pages, the musicfb.info6, invites users to install a browser extension, which was reported to send spam to the Facebook friends of those who installed it. This landing page received 24,623 impressions, 85 clicks, and spent around US$112.38. The domain musicfb.info was also promoted by other pages, accounting for 3% of all ads. We also find that the most popular landing pages are Facebook pages, accounting for 84% of all ads, followed by blackmattersus.com (7%), and Instagram (3.4%).

Figure 1: Number of ads created, their impressions, cost, and received clicks over time. Shaded region shows 2-month period just before the 2016 U.S. Election.

---

6An example of an ad is www.socially-divisive-ads.dcc.ufmg.br/app.php?query=2751
7We converted the ad spend cost to U.S. dollars as of May 19th. 1 USD = 61.33 RUB.
8https://web.archive.org/web/20161019155736/https://musicfb.info/
9https://www.wired.com/story/russia-facebook-ads-skechty-chrome-extension/
WordStream released a report as of April 2018\(^8\) which shows the average CTR for Facebook ads across all industries is 0.9%. As an example, Retail is 1.6%, Fitness is 1%, Health care 0.8%, and Finance is 0.56%. This means that these political ads have a CTR that is about an order of magnitude higher than a typical Facebook ad.

2.5 High Impact Ads

Our analyses reveal that only a few ads are responsible for most of the cost, impressions, and clicks. Considering this, we defined a set of high impact ads as the union of the top 10% ads in terms of cost, impressions, clicks, and CTR. We obtained 905 high impact ads, corresponding to 27.7% of the entire dataset. These ads account together to 83.9% of the total number of impressions, 81.8% of clicks, 88.5% of cost, and 46.9% of the CTR. For the purposes of our study, where we require manual inspection of the ads (to identify their targets and to run surveys), our ensuing analyses concern those high impact ads run before the 2016 U.S. elections: 485 ads.

2.6 Summary

This section describes and characterizes the ads in the IRA dataset. Our analysis highlights the landing pages that paid for the ads, and identifies the most successful ads in terms of impressions and clicks. We find that the ad campaigns were intensified near to the U.S. election period. Among our main findings, we show that the typical CTR for these ads is an order of magnitude higher than typical values for Facebook, meaning that these ads were very effective.

3 ANALYZING DIVISIVENESS OF THE ADS

To investigate whether these ads were designed to be ideologically divisive – that is, designed to elicit different reactions from people with different political viewpoints – we conducted three U.S. census-representative surveys (\(n = 2,886\)). We used each survey to measure one of three axes along which ads could potentially be divisive: 1) reporting: whether respondents would report the ads\(^9\), and on what basis they find the ad inappropriate to be reported, 2) approval and disapproval: whether they approve or disapprove the content

\(^8\)https://www.wordstream.com/blog/ws/2017/02/28/facebook-advertising-benchmarks

\(^9\)Reporting was measured as a binary variable
of the ad\textsuperscript{10}, and 3) false claims: if they are able to identify any false claims in the content of the ad\textsuperscript{11}.

Our surveys considered only those 485 high impact ads which were run before the elections. Each survey showed ten ads followed by demographic questions. The survey questions were pre-tested using cognitive interviews to ensure validity of measurement \cite{3}.

We measured overall ideological divisiveness on the three axes (reporting, approval, and false claims) using two metrics:

**Within-group divisiveness.** Within-group divisiveness measures the extent to which respondents’ answers about a particular ad are consistent with their political ideology. That is, do all liberals answer similarly about a particular ad. For each ad, we first calculate the standard deviation of all the responses, and then we calculate the standard deviation of the responses within a particular ideological group. Next, we compute within-group divisiveness as the fraction of within-group standard deviation to overall standard deviation. Therefore we interpret values lower than 1 as lower divisiveness (and greater agreeableness) within a group than overall, and values greater than 1 as greater within-group divisiveness than overall.

**Between-group divisiveness.** Between-group divisiveness measures the extent to which answers from respondents of one political ideology differ from answers of respondents who align with another political ideology. That is, do the liberals answer differently about a particular ad than the conservatives. For an ad, we calculate the difference between the mean responses per ideological group, and then compute the fraction of this difference over the maximum possible difference given the range of values to obtain the between-group divisiveness measure. This limits the range of between-group divisiveness measure between 0 and 1, where higher values indicate greater divisiveness between ideological groups.

Table 2 summarizes the divisiveness of the high impact ads. We find that the within-group divisiveness measure is lower than 1 for all our surveys. This indicates high agreeableness within the ideological groups. In addition, about 20% of the ads show between-group divisiveness higher than 0.5, indicating severe divisiveness for those ads between ideological groups.

### 3.1 Likelihood of reporting the ads

The first axis of divisiveness that we explored was reporting. We surveyed respondents regarding: 1) Whether they would report

\textsuperscript{10}Approval was measured on a 5-point scale from strong disapproval to strong approval.

\textsuperscript{11}Respondents were first asked whether a false claim was present in the ad and then asked to highlight that claim.

</tbody>
</table>

Figure 4: Reporting proportion and reasons of inappropriateness for the high impact ads.
Next, to examine ideological divisiveness, we find that the within-group divisiveness averages at 0.87 (stdev = 0.47) for liberals and at 0.90 (stdev = 0.43) for conservatives, suggesting lower than overall divisiveness and greater within-group agreeableness. This is also demonstrated by Figure 5 where we find that the respondents from the two ideological groups disagree about reporting several ads. About 50% of the ads show a between-group divisiveness of 0.2 or higher. Table 3 shows a few examples of the ads which showed the greatest differences in the reporting behavior by the respondents of two political ideologies.

Figure 5 (a, b) shows the distribution of the reporting proportions across ideological groups. We find significant differences in terms of the reporting behavior across political ideologies. Defining a median threshold for divisiveness, we find that in over 50 percent of the ads, the liberals and conservatives completely disagreed with each other (eg. conservatives showing more than their median reported proportion and liberals showing less than their median reported proportion, and the vice versa). Table 3 shows a few examples of the ads which showed the greatest differences in the reporting behavior by the respondents of two political ideologies. These ads typically mention politically-charged topics. For example, immigration — “TAG YOUR PHOTOS WITH #TXagainst Send us the reason why don’t you want illegals in Texas. Comments, photos, and videos are welcomed!”  — in this case presenting a viewpoint associated with the republican party, Or police brutality — “Police are beyond out of control, help us make this viral! Follow our account in order to spread the truth!”  — in this case presenting a viewpoint associated with the democratic party.

3.2 Approving content of the ads

With an objective to characterize the ads on the basis of what kinds of reactions they elicited, in our second survey we asked the respondents, whether they approve or disapprove a particular ad, and how strongly do they approve or disapprove. These two questions in the survey are modified from questions about political preference that have been extensively pre-tested by Pew Research for previous surveys about political polarization [3]. 24 respondents reported their approval of each ad, on average (stdev 1.9). We find that 87% of the ads were approved and 63% of the ads were disapproved by at least 20% respondents (see Figure 6 (a)). To quantify the received responses, we assigned an approval score on a 5 point scale with values of -2 (strong disapproval), -1 (weak disapproval), 0 (neither approve or disapprove), +1 (weak approval), and +2 (strong approval). While computing the mean approval score for a group, we dropped the 0 responses to ensure that a mean approval score close to 0 corresponds to similar weights from approval and disapproval. Next, to understand whether ideological perceptions influence in the approving behavior of respondents, we plot Figures 6 (c&d)

Table 3: Example ads on the basis of reporting behavior by the respondents from two political ideologies.

</tr>
</tbody>
</table>

Table 6: 3.3 Perceptions of false claims in the ads

To examine if the high impact IRA ads contained any false claims, in another survey we asked the respondents if they could identify any false claims present in the ads. 23 respondents reported their perception of false claims of each ad, on average (stddev = 3.28). We find that 89% (343 out of 485) of the high impact ads were identified to have at least one false claim, and about 45% of the ads contained false claims according to 10% of the respondents. Figure 7 (a) shows the cumulative distribution of the ads with the number of respondents who identified at least one false claim in them.

Next, like in the other two content analyses, we examine if the ideological opinion influenced individuals’ perceptions about false claims in ads. Figure 7 (b) shows evidences about the same. Further, the within-group divisiveness measure of 0.66 (stddev = 0.68) for liberals and 0.86 (stddev = 0.63) for conservatives suggests greater agreeableness within ideological groups than across them. Table 5 shows a few ads highlighted with their false claims that the respondents from the two ideological groups identified in our survey.

4.1 Targeting Possibilities

The Facebook ads platform provides three approaches for advertisers to target people [18], briefly described next.

**Personolly Identifiable Information (PII)** target is the form in which advertisers provide personal information about users such as name, phone number, and email address so that Facebook can directly place the ads to them. This kind of targeting does not appear in the IRA dataset.

**Look-alike audience target.** For this targeting option, advertisers provide to Facebook a list of users quite similar to that one in the PII or a list of people who liked the advertiser Facebook page. Then, Facebook attempt to target a similar audience to the group in this specific list. Only 1.1% of the high impact ads used this option.

**Attribute-based targeting** allows the advertiser to create a target formula based on a wide range of elements that include user basic demographics (i.e. gender, age, location, language), advanced demographics (i.e. political leaning, income level, ‘Parents with children preschoolers’), interests (i.e. newspapers, religion, politics), and behaviors (i.e. ‘Business Travelers’ or ‘New Vehicle buyers’). Recent work showed that the amount of possible interests provide by Facebook is greater than 240 thousand [18]. Facebook allows one to include or exclude users with each of those attributes and combine multiple attributes as part of a target formula. The vast majority of the high impact ads, 895 out of the 905, used this option to elaborate a formula. Particularly, we noted that 91.2% of these ads contain interests and behaviors, which are attributes that Facebook suggests as part of its interface. We found that 78% of the ads used 2 or more interests and behaviors in their formula, creating very complex formulas with up to 39 distinct attributes.

Figure 8 shows the top attributes that appear in the ads target formula based on the number of times they appeared in different ads. There were 497 distinct attributes and the most present attributes interest were African-American history and African-American Civil Rights Movement (1954-68), appearing in 295 (32%) ads. We can note a prevalence of attributes related to African-American and Hispanic Population, with interests like Mexico, ‘Hispanidad’ and ‘Latin hip hop’. Next, we investigate aspects of the Facebook ads platform design that might have favored the IRA ads to massively explore this particular targeting strategy.

Figure 8: Top 20 attributes based on the number of advertisements they appeared.

4.2 The Role of Attribute Suggestions

Facebook provides a tool for advertisers that, given a target attribute, it presents a list of other attributes that target people with similar demographic aspects [18]. For example, in the list of suggested targeting interests for ‘Townhall.com’, a page with an audience in which 79.5% of the users are very conservative users according to Facebook, there are other pages with similar bias towards very conservative users, i.e. ‘The Daily Caller’ (67.1%), ‘RedState’ (84.3%), and ‘TheBlaze’ (59.6%) [16].

In order to investigate if the IRA ads have used suggestions to elaborate complex targeting formulas, we crawled the attribute suggestions for each attribute that appear in the dataset of highly impact ads. Figure 9 shows the cumulative distribution function for the number of suggested attributes that appear in the same formula. We can see that around 64% of the ads that used this feature have at least three target attributes suggested by Facebook as part of the same formula. There are 1.2% of ads with more than 10 suggested attributes in the same formula. As an example, all the 13 interests, including Islam, Ramadan, Islamism, used in the target formula of the ad ID 1915 [18] appear as suggestions for at least one of the others in the formula. For ad ID 1840 [18], we were able to find 9 out of 10 of the interests using the interest suggestion feature. This provides evidence that this feature may have been a key element used by the IRA campaign to choose the target audience.

4.3 Summary

In this Section we show that the vast majority of the IRA ads use attribute-based targeting, containing complex target formula that includes interest and behavioral attributes that are likely suggested by Facebook. Next, we investigate the extent to which these formulas allowed advertisers to reach demographic biased audiences.

5 ANALYZING THE TARGET AUDIENCE

We start by describing our methodology to reproduce the IRA queries (without running the ad) and gather the demographics of the of the targeted users.

---

5.1 Assessing the Audience Demographics

Before launching an advertisement in Facebook, the advertiser can get the estimated audience (i.e., number of monthly active users) likely to match the target formula. Our methodology consists of using the Facebook Marketing API14 to reproduce the targeting formula of all high impact IRA ads and, without running any ad on Facebook, get the demographics of the population that matches each targeting formula. This methodology has been extensively used recently for different purposes, including inferring news outlets political leaning [16], study migration [21] and gender bias [9] across countries, and for public health awareness [17] and lifestyle disease surveillance [2]. For our analysis, we considered seven demographic categories: political leaning, race, gender, education level, income, location (in terms of states), and age. As a baseline for comparison, we also gathered the demographic distribution of the United States Facebook population.

Only 11% of the used attributes that appear in the IRA ads targeting formulas are not available for targeting anymore due to changes in the Facebook Marketing API. In most of these cases, we reproduced the ad target formula without the missing attribute, specially when the attribute looks redundant with the others in the formula. We did not reproduce only 6 targeting formulas.

5.2 Measuring Audience Bias

To assess the audience bias of each of the demographic aspects considered, we compute the differences between the fraction of the population with a demographic aspect and the same fraction of the population in the baseline distribution (i.e., the United States Facebook population).

Figure 10 depicts the measured bias distribution for two demographic categories: political leaning and race. The median is represented by a white dot in the center line of the violin. In comparison with all the demographic category, these two showed to be the ones with the highest biases. We can note that most of the ads target audiences that are more biased towards African-Americans population and liberals. About 70% of the IRA ads target an audience with a higher proportion of African-Americans than in the US Facebook distribution. This difference is even accentuated for liberals, with 82% more biased in comparison with the reference distribution. The percentage of ads with bias score superior to 0.15 is 52% for African-American and 41% for Liberals. Interestingly, although they are not the majority, there are ads that target very biased populations of conservatives, liberals, Hispanic, but specially African-Americans. The target audiences for the IRA ads are slightly biased towards women and young people (18-34 years), which are omitted from Figure 10 due to space constraints.

5.3 Targeting audience and Divisiveness

Next, we investigate if the advertisers target the ads towards audiences that are less likely to identify their inappropriateness due to their ideological perception bias. Additionally, we examine if the ads directed to biased audiences could leverage the already existing societal divisiveness to further amplify it among the masses.

To understand these nuances of targeted advertising, in this section, we focus on the relationship between the targeted population and the ideological divisiveness in reporting, approval, and false claim identifying behaviors for the ads. Table 6 reports the correlation values between the targeted population and the tendency of the population to report, approve, and identify false claims.

*Figure 10: Bias in demographic dimensions.*

Table 6: Pearson's r correlation between targeting and the ideological divisiveness for the high impact ads (***(p < 0.001, correlation revealed no statistical significance in the case of false claims).*)

82% more biased in comparison with the reference distribution. The percentage of ads with bias score superior to 0.15 is 52% for African-American and 41% for Liberals. Interestingly, although they are not the majority, there are ads that target very biased populations of conservatives, liberals, Hispanic, but specially African-Americans. The target audiences for the IRA ads are slightly biased towards women and young people (18-34 years), which are omitted from Figure 10 due to space constraints.

5.4 Summary

Our findings show that the IRA ads reached audiences that are very biased towards African-Americans and liberals. More important,
As a final contribution, we have deployed a system (available at http://www.socially-divisive-ads.dcc.ufmg.br/) that displays the ads and their computed information such as the demographics of their targeting audiences.
